Syntax and Semantics

Syntax - describes what constructions are possible in the language, what is a correct program and what is not

Semantics – describes what these constructions mean, e.g., what computer does when it performs given commands

Java distinguishes between two types of errors:

Compile time errors: They are produced by compiler.

These errors are either

- syntax for example missing ;
- semantic for example assignment between incompatible types
- **Run time errors:** They are produced by Java Virtual Machine during execution of a program. Java contains no dangerous constructions, always an **exception** is generated.

Overview of the Syntax of Java

- The programs consist of classes.
- Each class consists of definitions of data and instructions for a certain kind of **objects**.
 - fields (attributes): data of an object
 - methods: instructions that manipulate with these data (also called functions or procedures in other languages)
- A method consists of a header that defines its name, arguments, return type, ... and body that contains statements.
- Statements manipulate with data stored in variables either in fields or in local variables.
- Execution of statements includes evaluation of expressions. The values of expressions are then assigned into variables.
- Each variable, value and expression is of some type.
- On the lowest level a program is a sequence of lexical elements (tokens).

Lexical Elements

White space characters and comments are ignored:

- white space characters: space (SP), horizontal tab (HT), form feed (FF), newline (LF), carriage return (CR)
- comments: /* this is a comment */

Basic types of lexical elements (tokens) are:

- identifiers: x dist1 System9 number_of_elements
- keywords: while float int public class
- Iiterals: 124 true 'd' "hello"
- separators: () { } [] ; : , .
- operators: + * / && = *= < >>=

Literals

integer literals: 237L 033 OxDadaCafe 1996 Ox00FF00FF \mathbf{O} floating point literals: 1e1 2. .3 0.0 3.14f 1.213e-9 1E137D boolean literals: true false character literals: 'a' '%' '\t' '\\' '\'' '\177' '\u03a9' string literals: "\"" "This is a string." "\r\n" 11 11 the null literal: null

Possible **escape sequences** in character and string literals:

• \b \t \n \f \r \" \' \\ \177 \u2B97

Keywords

abstract boolean break byte case catch char class const continue default do double else extends final finally float

for goto if implements import instanceof int interface long native new package private protected public return short static

strictfp super switch synchronized this throw throws transient try void volatile while

Comments

Java supports three kinds of comments:

One-line comment – the compiler ignores everything from the "//" to the end of line.

// This is a one-line comment.

- Multi-line comment the compiler ignores everything from the "/*" to an occurrence of "*/".
 Note: "/*/" is not a valid comment.
 - /* This is a comment that
 continues across lines. */
- Documentation comment the compiler ignores everything from the "/**" to an occurrence of "*/". javadoc tool generates documentation based on content of the comment.
 - /** This is a documentation comment.
 - * The comment may contain html tags as well as special
 - * tags that begin with the '@' sign. */

Types, Values and Variables

Variables are used by program to hold data. Each variable used in program must be explicitly specified by its data type and name. Java has two kinds of data types: reference and primitive.

Primitive

A variable of primitive type contains a **single value** of the appropriate size and format for its type: a number, a character or a boolean value.

```
boolean b = true;
int i = 456;
float f = 2.71828;
```

Reference

The value of a reference type variable, in contrast to that of a primitive type, is a **reference** to (an address of) an object or an array.

```
Hashtable h = new Hashtable();
int[] a = new int[20];
```

Integral Types and Values

Туре	Range	Size [bits]
byte	-128127	8
short	-3276832767	16
int	-21474836482147483647	32
long	-92233720368547758089223372036854775807	64
char	065535	16

Possible operations on integer values are:

- the comparison operators (<, <=, >, >=, ==, !=)
- the unary plus and minus (+, -)
- the binary arithmetic operators (+, -, *, /, %)
- the prefix and postfix increment and decrement operators (++, --)
- the signed and unsigned shift operators (<<, >>, >>>)
- the bitwise complement operator (~)
- the integer bitwise operators (&, |, ^)

Floating-Point Types and Values

The floating-point values are numbers of the form $sm2^e$ where

Туре	S	m	е	Size [bits]
float	-1, 1	02^{24} –1	-149104	32
double	-1, 1	$02^{53}-1$	-1075970	64

Туре	Min. value	Max. value
float	1.40239846e-45f	3.40282347e+38f
double	4.94065645841246544e-324	1.79769313486231570e+308

Possible operations on floating-point values are:

- the comparison operators (<, <=, >, >=, ==, !=)
- the unary plus and minus (+, -)
- the binary arithmetic operators (+, -, *, /, %)
- the prefix and postfix increment and decrement operators (++, --)

The Boolean Type and Values

The type **boolean** has two possible values: **true** and **false**

Possible operations on floating-point values are:

- the relational operators (==, !=)
- the logical complement operator (!)
- the binary logical operators (&, |, ^)
- the conditional-and and conditional-or operators (&&, ||)
- the ternary conditional operator (?:)

Boolean expressions determine the control flow in several kinds of statements:

- the if statement
- the while statement
- the do statement
- the for statement
